MODEL CATEGORY STRUCTURES ARISING FROM DRINFELD VECTOR BUNDLES

SERGIO ESTRADA, PEDRO A. GUIL ASENSIO, MIKE PREST, AND JAN TRLIFAJ

Abstract. We present a general construction of model category structures on the category $\mathcal{C}(\Omega\mathcal{C}(X))$ of unbounded chain complexes of quasi-coherent sheaves on a semi-separated scheme $X$. The construction is based on making compatible the filtrations of individual modules of sections at open affine subsets of $X$. It does not require closure under direct limits as previous methods. We apply it to describe the derived category $\mathcal{D}(\Omega\mathcal{C}(X))$ via various model structures on $\mathcal{C}(\Omega\mathcal{C}(X))$. As particular instances, we recover recent results on the flat model structure for quasi-coherent sheaves. Our approach also includes the case of (infinite-dimensional) vector bundles, and of restricted flat Mittag-Leffler quasi-coherent sheaves, as introduced by Drinfeld. Finally, we prove that the unrestricted case does not induce a model category structure as above in general.

1. Introduction

Let $X$ be a scheme and $\Omega\mathcal{C}(X)$ the category of all quasi-coherent sheaves on $X$. A convenient way of approaching the derived category $\mathcal{D}(\Omega\mathcal{C}(X))$ goes back to Quillen [27], and consists in introducing a model category structure on $\mathcal{C}(\Omega\mathcal{C}(X))$, the category of unbounded chain complexes on $\Omega\mathcal{C}(X)$. In particular, one can compute morphisms between two objects $X$ and $Y$ of $\mathcal{D}(\Omega\mathcal{C}(X))$ as the $\mathcal{C}(\Omega\mathcal{C}(X))$-morphisms between cofibrant and fibrant replacements of $X$ and $Y$, respectively, modulo chain homotopy.

Recently, Hovey has shown that model category structures naturally arise from small cotorsion pairs over $\mathcal{C}(\Omega\mathcal{C}(X))$, [20]. Since $\Omega\mathcal{C}(X)$ is a Grothendieck category [8], there is a canonical injective model category structure on $\mathcal{C}(\Omega\mathcal{C}(X))$. However, this structure is not monoidal, that is, compatible with the tensor product on $\Omega\mathcal{C}(X)$, [21, pp. 111-2]. Another natural, but not monoidal, model structure on $\mathcal{C}(\Omega\mathcal{C}(X))$ was constructed in [22] under the assumption of $X$ being a Noetherian separated scheme with enough locally frees.

The lack of compatibility with the tensor product was partially solved in [14, 25] by using flat quasi-coherent sheaves. The main result of [14] shows that in case $X$ is quasi-compact and semi-separated, it is possible to construct a monoidal flat model structure on $\mathcal{C}(\Omega\mathcal{C}(X))$. The weak equivalences of this model structure are the same as the ones for the injective model structure, hence they induce the same cohomology functors (see [25] for a different approach). However, the structure of flat quasi-coherent sheaves is rather complex, and it is difficult to compute the associated fibrant and cofibrant replacements. Moreover, the methods of [14] depend heavily on the fact that the class of all flat modules is closed under direct limits.

Date: June 27, 2009.

Key words and phrases. Drinfeld vector bundle, model category structure, flat Mittag-Leffler module.

The first two authors have been partially supported by the DGI and by the Fundación Seneca. The fourth author supported by GACR 201/09/0816 and MSM 0021620839.
A different approach has recently been suggested in [10] for the particular case of quasi-coherent sheaves on the projective line $\mathbb{P}^1(k)$. In that paper it was shown that the class of infinite-dimensional vector bundles (i.e., those quasi-coherent sheaves whose sections in all open affine sets are projective) imposes a monoidal model category structure on $\mathcal{C}(\mathcal{Qco}(\mathbb{P}^1(k)))$. The proofs and techniques in [10] are strongly based on the Grothendieck decomposition theorem for vector bundles over the projective line [18], hence they cannot be extended to more general situations.

In the present paper, we show that the main results of [10] and [14] are particular instances of the following general theorem that provides for a variety of model category structures on $\mathcal{C}(\mathcal{Qco}(X))$ parametrized by sets $S_v$ ($v \in V$) of modules of sections (see Section 4 for unexplained terminology):

**Theorem 1.1.** Let $X$ be a semi-separated scheme. There is a model category structure on $\mathcal{C}(\mathcal{Qco}(X))$ in which the weak equivalences are the homology isomorphisms, the cofibrations (resp. trivial cofibrations) are the monomorphism with cokernels in $\text{dg}\mathcal{C}$ (resp. $\mathcal{C}$), and the fibrations (resp. trivial fibrations) are the epimorphisms whose kernels are in $\text{dg}\mathcal{C}^\perp$ (resp. $\mathcal{C}^\perp$). Moreover, if every $M \in S_v$ is a flat $\mathcal{R}(v)$-module, and $M \otimes_{\mathcal{R}(v)} N \in S_v$ for all $M, N \in S_v$, then the model category structure is monoidal.

The proof of Theorem 1.1 is based on new tools for handling filtrations of quasi-coherent sheaves developed in this paper. Thus it avoids the usual assumption of closure under direct limits.

Theorem 1.1 immediately yields the following generalization of [10, Theorem 6.1]:

**Corollary 1.2.** Let $X$ be a scheme having enough infinite-dimensional vector bundles (for example, a quasi-compact and quasi-separated scheme that admits an ample family of invertible sheaves, or a noetherian, integral, separated, and locally factorial scheme). Let $\mathcal{C}$ be the class of all vector bundles on $X$.

Then there is a monoidal model category structure on $\mathcal{C}(\mathcal{Qco}(X))$ where weak equivalences are homology isomorphisms, the cofibrations (trivial cofibrations) are the monomorphisms whose cokernels are $\text{dg}\mathcal{C}^\perp$ (resp. $\mathcal{C}^\perp$). Moreover, if every $M \in S_v$ is a flat $\mathcal{R}(v)$-module, and $M \otimes_{\mathcal{R}(v)} N \in S_v$ for all $M, N \in S_v$, then the model category structure is monoidal.

Similarly, we immediately recover [14, Theorem 6.7]:

**Corollary 1.3.** Let $X$ be a scheme with enough flat quasi-coherent sheaves (for instance, let $X$ be quasi-compact and semi-separated, see [25, Proposition 16]). Then there is a monoidal model category structure on $\mathcal{C}(\mathcal{Qco}(X))$ where weak equivalences are homology isomorphisms, the cofibrations (trivial cofibrations) are the monomorphisms whose cokernels are $\text{dg}$-complexes of vector bundles (exact complexes of vector bundles whose every cycle is a vector bundle), and the fibrations (trivial fibrations) are the epimorphisms whose kernels are in $\text{dg}\mathcal{C}^\perp$ ($\mathcal{C}^\perp$).

However, there are further interesting applications of Theorem 1.1. Drinfeld has proposed quasi-coherent sheaves whose sections at affine open sets are flat and Mittag-Leffler modules (in the sense of Raynaud and Gruson [26]) as the appropriate objects defining infinite-dimensional vector bundles on a scheme, see [2, p.266]. Here we call such quasi-coherent sheaves the Drinfeld vector bundles, and show that the restricted ones (bounded by a cardinal $\kappa$) fit into another instance of Theorem 1.1:

**Corollary 1.4.** Let $X$ be a semi-separated scheme possessing a generating set $\mathcal{G}$ of Drinfeld vector bundles. Let $\kappa$ be an infinite cardinal such that $\kappa \geq |E|$ (in the notation of Section 3) and each $M \in \mathcal{G}$ is $\leq \kappa$-presented. For each $v \in V$, let $S_v$
denote the class of all \( \leq \kappa \)-presented flat Mittag-Leffler modules. Denote by \( \mathcal{C} \) the class of all Drinfeld vector bundles \( \mathcal{M} \) such that \( \mathcal{M}(v) \) has a \( S_v \)-filtration for each \( v \in V \).

Then there is a monoidal model category structure on \( \mathcal{C}(\Omega \mathcal{O}(X)) \) where weak equivalences are homology isomorphisms, the cofibrations (trivial cofibrations) are monomorphisms with cokernels in \( d \mathcal{G} (\mathcal{C}) \), and the fibrations (trivial fibrations) are epimorphisms whose kernels are in \( d \mathcal{G} (\mathcal{C}) \).

The reader may wonder whether it is possible to apply Theorem 1.1 to the entire class of Drinfeld vector bundles and impose thus a (monoidal) model category structure on \( \mathcal{C}(\Omega \mathcal{O}(X)) \). Our final theorem shows that this is not the case in general. We adapt a recent consistency result of Eklof and Shelah [6] concerning Whitehead groups to this setting, and prove (in ZFC):

**Theorem 1.5.** The class \( \mathcal{D} \) of all flat Mittag-Leffler abelian groups is not precoversing. Thus \( \mathcal{D} \) cannot induce a cofibrantly generated model category structure on \( \Omega \mathcal{O}(\text{Spec}(Z)) \cong \text{Mod}-Z \) compatible with its abelian structure.

## 2. Notation and Preliminaries

Let \( \mathcal{A} \) be a Grothendieck category. A well-ordered direct system of objects of \( \mathcal{A} \), \((A_\alpha \mid \alpha \leq \lambda)\), is said to be continuous if \( A_0 = 0 \) and, for each limit ordinal \( \beta \leq \lambda \), we have \( A_\beta = \lim A_\alpha \) where the limit is taken over all ordinals \( \alpha<\beta \). A continuous direct system \((A_\alpha \mid \alpha \leq \lambda)\) is called a continuous directed union if all morphisms in the system are monomorphisms.

**Definition 2.1.** Let \( \mathcal{L} \) be a class of objects of \( \mathcal{A} \). An object \( A \) of \( \mathcal{A} \) is \( \mathcal{L} \)-filtered if \( A = \lim A_\alpha \) for a continuous directed union \((A_\alpha \mid \alpha \leq \lambda)\) satisfying that, for each \( \alpha + 1 \leq \lambda \), \( \text{Coker} (A_\alpha \to A_{\alpha+1}) \) is isomorphic to an element of \( \mathcal{L} \).

We denote by \( \text{Filt}(\mathcal{L}) \) the class of all \( \mathcal{L} \)-filtered objects in \( \mathcal{A} \). A class \( \mathcal{L} \) is said to be closed under \( \mathcal{L} \)-filtrations in case \( \text{Filt}(\mathcal{L}) = \mathcal{L} \).

**Definition 2.2.** Let \( \mathcal{D} \) be a class of objects of \( \mathcal{A} \). We will denote by \( \mathcal{D}^\perp \) the subclass of \( \mathcal{A} \) defined by

\[
\mathcal{D}^\perp = \text{KerExt}^1(\mathcal{D},-) = \{ Y \in \text{Ob}(\mathcal{A}) \mid \text{Ext}^1(\mathcal{D},Y) = 0, \text{ for all } D \in \mathcal{D} \}.
\]

Similarly,

\[
\perp \mathcal{D} = \text{KerExt}^1(-,\mathcal{D}) = \{ Z \in \text{Ob}(\mathcal{A}) \mid \text{Ext}^1(Z,\mathcal{D}) = 0, \text{ for all } D \in \mathcal{D} \}.
\]

Analogously, we will define

\[
\mathcal{D}^{\perp \infty} = \{ Y \in \text{Ob}(\mathcal{A}) \mid \text{Ext}^i(\mathcal{D},Y) = 0, \text{ for all } D \in \mathcal{D} \text{ and } i \geq 1 \}
\]

and

\[
\perp \infty \mathcal{D} = \{ Z \in \text{Ob}(\mathcal{A}) \mid \text{Ext}^i(Z,\mathcal{D}) = 0, \text{ for all } D \in \mathcal{D} \text{ and } i \geq 1 \}.
\]

Let us recall the following definitions from [16].

**Definition 2.3.** A pair \((\mathcal{F},\mathcal{C})\) of classes of objects of \( \mathcal{A} \) is called a cotorsion pair if \( \mathcal{F}^\perp = \mathcal{C} \) and if \( \perp \mathcal{C} = \mathcal{F} \). The cotorsion pair is said to have enough injectives (resp. enough projectives) if for each object \( Y \) of \( \mathcal{A} \) there exists an exact sequence \( 0 \to Y \to C \to F \to 0 \) (resp. for each object \( Z \) of \( \mathcal{A} \) there exists an exact sequence \( 0 \to C' \to F' \to Z \to 0 \)) such that \( F,F' \in \mathcal{F} \) and \( C,C' \in \mathcal{C} \). A cotorsion pair \((\mathcal{F},\mathcal{C})\) is complete provided it has enough injectives and enough projectives.

The proof of the following lemma is the same as for module categories (see [16, Lemma 2.2.10]).
Lemma 2.4. Let $\mathcal{A}$ be a Grothendieck category with enough projectives and let $(\mathcal{F}, \mathcal{C})$ be a cotorsion pair on $\mathcal{A}$. The following conditions are equivalent

a) If $0 \to F' \to F \to F'' \to 0$ is exact with $F, F'' \in \mathcal{F}$, then $F' \in \mathcal{F}$.

b) If $0 \to C' \to C \to C'' \to 0$ is exact with $C', C'' \in \mathcal{C}$, then $C' \in \mathcal{C}$.

c) $\text{Ext}^2(F, C) = 0$ for all $F \in \mathcal{F}$ and $C \in \mathcal{C}$.

d) $\text{Ext}^n(F, C) = 0$ for all $n \geq 1$ and all $F \in \mathcal{F}$ and $C \in \mathcal{C}$.

A cotorsion pair satisfying the equivalent conditions above is called hereditary. So $(\mathcal{F}, \mathcal{C})$ is a hereditary cotorsion pair, if and only if $\mathcal{F} = \perp \mathcal{C}$ and $\mathcal{C} = \mathcal{F}^\perp$.

We finish this section by recalling the notion of a Mittag-Leffler module from [26].

Definition 2.5. Let $R$ be a ring and $M$ a right $R$-module. Then $M$ is Mittag-Leffler provided that the canonical map $M \otimes_R \prod_{i \in I} M_i \to \prod_{i \in I} M \otimes_R M_i$ is monic for each family of left $R$-modules $(M_i \mid i \in I)$.

For example, all finitely presented modules, and all projective modules, are Mittag-Leffler. Any countably generated flat Mittag-Leffler module is projective. In fact, projectivity of a module $M$ is equivalent to $M$ being flat Mittag-Leffler and a direct sum of countably generated submodules (see [26] and [2, Theorem 2.2]).

We refer to [5, 16, 19, 21] for unexplained terminology used in this paper.

3. Filtrations of Quasi–Coherent Sheaves

Let $X$ be a scheme. Let $Q_X = (V, E)$ be the quiver whose set, $V$, of vertices is a subfamily of the family of all open affine sets of $X$ such that $V$ covers both $X$ and all intersections $O \cap O'$ of open affine sets $O, O'$ of $V$. The set of edges, $E$, consists of the reversed arrows $v \to u$ corresponding to the inclusions $u \subseteq v$ where $u$ and $v$ are in $V$. We say that $Q_X$ is a quiver associated to the scheme $X$. Note that this quiver is not unique, because different choices of the set of vertices $V$ may give rise to non-isomorphic quivers associated to the same scheme $X$.

As explained in [8, Section 2], there is an equivalence between the category of quasi–coherent sheaves on $X$ and the category of quasi–coherent $\mathcal{R}$–modules where $\mathcal{R}$ is the representation of the quiver $Q_X$ by the sections of the structure sheaf $\mathcal{O}_X$. A quasi–coherent sheaf $\mathcal{F}$ on $X$ corresponds to a quasi–coherent $\mathcal{R}$–module $M$ defined by the following data:

1. An $\mathcal{R}$–module on $X$, that is, an $\mathcal{R}(u)$–module $M_u$, for each $u \in V$ and a $\mathcal{R}(u)$–morphism $\rho_{uv} : M_u \to M_v$ for each edge $u \to v$ in $E$;

2. The quasi–coherence condition, saying that the induced morphism

$$id_{\mathcal{R}(v)} \otimes \rho_{uv} : \mathcal{R}(v) \otimes_{\mathcal{R}(u)} M_u \to \mathcal{R}(v) \otimes_{\mathcal{R}(v)} M_v \cong M_v$$

is an $\mathcal{R}(v)$–isomorphism, for each arrow $u \to v$ in $E$;

3. The compatibility condition, saying that if $w \subseteq v \subseteq u$, with $w, v, u \in V$, then $\rho_{uw} = \rho_{uv} \circ \rho_{wv}$.

Note that quasi–coherent subsheaves $\mathcal{F}'$ of $\mathcal{F}$ correspond to quasi–coherent $\mathcal{R}$–submodules $M'$ of $M$ (where the latter means that $M'_u$ is an $\mathcal{R}(u)$–submodule of $M_v$ and the map $\rho'_{uv}$ is a restriction of $\rho_{uv}$ for each edge $u \to v$ in $E$). If $(\mathcal{F}_i)_{i \in I}$ are quasi–coherent subsheaves of $\mathcal{F}$ then $\mathcal{F}' = \sum_{i \in I} \mathcal{F}_i$ (resp. $\mathcal{F}' = \mathcal{F}_1 \cap \mathcal{F}_2$) corresponds to the quasi–coherent submodule $M'$ such that $M'_u = \sum_{i \in I} (M_i)_v$ (resp. such that $M'_u = (M_1)_v \cap (M_2)_v$) and the maps $\rho'_{uv}$ are restrictions of $\rho_{uv}$.

Recall that $\mathcal{QcO}(X)$ denotes the category of all quasi–coherent sheaves on $X$. This is a Grothendieck category by [8, p.290]. Note that in our setting, if $u \subseteq v$ are affine open subsets in $V$, then $\mathcal{R}(u)$ is a flat $\mathcal{R}(v)$–module, see [19, III.9].
Recall that a quasi-coherent sheaf $M$ on $X$ is a (classical algebraic) vector bundle if $M(u)$ is a free $\mathcal{O}(u)$-module of finite rank for every open affine set $u$. In this paper we adopt the following more general definition: $M$ is a vector bundle if $M(u)$ is a (not necessarily finitely generated) projective $\mathcal{O}(u)$–module for each open affine set $u$ (see [2, §2. Definition]).

In [2, Section 2. Remarks], Drinfeld proposed to consider the following more general notion of a vector bundle (see also [3, Appendices 5 and 6]). Thus, we call a quasi–coherent sheaf $M$ a Drinfeld vector bundle provided that $M(u)$ is a flat Mittag–Leffler $\mathcal{O}(u)$–module for each open affine set $u$ (cf. [2, p. 266]).

One of the main goals of this paper is to construct monoidal model category structures associated to these generalized notions of vector bundles. In order to achieve this aim we will need to characterize these classes as closures under filtrations of certain of their subsets.

The following tools will play a central role in our study of these filtrations, both in the case of modules over a ring, and of quasi-coherent sheaves on a scheme.

The first tool is known as Eklof’s Lemma (see [4, Theorem 1.2]):

**Lemma 3.1.** Let $R$ be a ring and $C$ be a class of modules. Let $M$ be a module possessing a $\perp C$-filtration. Then $M \in \perp C$.

**Remark 3.2.** The proof of Lemma 3.1 given in [16, Lemma 3.1.2] needs only embeddability of each module into an injective one, so the lemma holds in $\mathcal{Qco}(X)$, and in fact in any Grothendieck category.

Our second tool is known as Hill’s Lemma (see [16, Theorem 4.2.6], [28, Lemma 1.4], or [30, Theorem 6]). It will allow us to extend a given filtration of a module $M$ to a complete lattice of its submodules having similar properties.

**Lemma 3.3.** Let $R$ be a ring, $\lambda$ a regular infinite cardinal, and $J$ a class of $<\lambda$-presented modules. Let $M$ be a module with a $J$-filtration $M = (M_\alpha \mid \alpha \leq \sigma)$. Then there is a family $\mathcal{H}$ consisting of submodules of $M$ such that

1. $M \subseteq \mathcal{H}$,
2. $\mathcal{H}$ is closed under arbitrary sums and intersections,
3. $P/N$ has a $J$-filtration for all $N, P \in \mathcal{H}$ such that $N \subseteq P$, and
4. If $N \in \mathcal{H}$ and $T$ is a subset of $M$ of cardinality $<\lambda$, then there exists $P \in \mathcal{H}$ such that $N \cup T \subseteq P$ and $P/N$ is $<\lambda$-presented.

We will also need the following application of Lemma 3.3 (see [16, Theorem 4.2.11] and [30, Theorem 10]):

**Lemma 3.4.** Let $R$ be a ring, $\lambda$ a regular uncountable cardinal, and $J$ a class of $<\lambda$-presented modules. Let $\mathcal{A} = \perp (J^\perp)$, and let $\mathcal{A}^{<\lambda}$ denote the class of all $<\lambda$-presented modules from $\mathcal{A}$. Then every module in $\mathcal{A}$ is $\mathcal{A}^{<\lambda}$-filtered.

If $\kappa$ is a cardinal and $M$ a quasi-coherent sheaf, then $M$ is called locally $\leq \kappa$-presented if for each $v \in V$, the $\mathcal{O}(v)$-module $M(v)$ is $\leq \kappa$-presented. Notice that if $\kappa \geq |V|$ and $\kappa \geq |\mathcal{O}(v)|$ for each $v \in V$, then this definition is equivalent to saying that $M$ is $\kappa^+$-presentable in the sense of [14, Lemma 6.1], and also to $|\bigoplus_{v \in V} M(v)| \leq \kappa$.

For future use in Section 4 we now present a version of Hill’s Lemma for the category $\mathcal{Qco}(X)$. For this version, we assume that $X$ is a scheme, $\lambda$ a regular infinite cardinal such that $\lambda > |V|$ and $\lambda > |\mathcal{O}(v)|$ for all $v \in V$, and $J$ a class of locally $<\lambda$-presented objects of $\mathcal{Qco}(X)$. Further, let $M$ be a quasi–coherent sheaf possessing a $J$-filtration $\mathcal{O} = (M_\alpha \mid \alpha \leq \sigma)$. 

By [9, Corollary 2.3], there exist locally \(<\lambda\)-presented quasi-coherent sheaves \(A_\alpha \subseteq M_{\alpha+1}\) such that \(M_{\alpha+1} = M_\alpha + A_\alpha\) for each \(\alpha < \sigma\). A set \(S \subseteq \sigma\) is called closed provided that \(M_\alpha \cap A_\alpha \subseteq \bigcup_{\beta, \alpha, \beta \in S} A_\beta\) for each \(\alpha \in S\).

**Lemma 3.5.** Let \(H = \{\sum_{\alpha \in S} A_\alpha \mid S \text{ closed}\}\). Then \(H\) satisfies the following conditions:

1. \(\emptyset \subseteq H\).
2. \(H\) is closed under arbitrary sums.
3. \(P/N\) has a \(J\)-filtration whenever \(N, P \in H\) are such that \(N \subseteq P\).
4. If \(N \in H\) and \(X\) is a locally \(<\lambda\)-presented quasi-coherent subsheaf of \(M\), then there exists \(P \in H\) such that \(N + X \subseteq P\) and \(P/N\) is locally \(<\lambda\)-presented.

**Proof.** Note that for each ordinal \(\alpha \leq \sigma\), we have \(M_\alpha = \sum_{\beta < \alpha} A_\beta\), hence \(\alpha\) is a closed subset of \(\sigma\). This proves condition (1). Since any union of closed subsets is closed, condition (2) holds.

In order to prove condition (3), we consider closed subsets \(S, T\) of \(\sigma\) such that \(N = \sum_{\alpha \in S} A_\alpha\) and \(P = \sum_{\alpha \in T} A_\alpha\). Since \(S \cup T\) is closed, we will w.l.o.g. assume that \(S \subseteq T\). We define a \(J\)-filtration of \(P/N\) as follows. For each \(\beta \leq \sigma\), let \(\mathcal{F}_\beta = (\sum_{\alpha \in T \cap \alpha < \beta} A_\alpha + N)/N\). Then \(\mathcal{F}_{\beta+1} = \mathcal{F}_\beta + (A_\beta + N)/N\) for \(\beta \in T\setminus S\) and \(\mathcal{F}_{\beta+1} = \mathcal{F}_\beta\) otherwise.

Let \(\beta \in T \setminus S\). Then \(\mathcal{F}_{\beta+1}/\mathcal{F}_\beta \cong A_\beta/(\sum_{\alpha \in T \cap \alpha < \beta} A_\alpha + N)\), and since \(\beta \in T \setminus S\) and \(T\) is closed, we have

\[
A_\beta \cap (\sum_{\alpha \in T \cap \alpha < \beta} A_\alpha + N) = A_\beta \cap (\sum_{\alpha \in S, \alpha > \beta} A_\alpha + \sum_{\alpha \in T, \alpha < \beta} A_\alpha) \\
\subseteq A_\beta \cap (\sum_{\alpha \in S, \alpha > \beta} A_\alpha + (M_\beta \cap A_\beta)) \subseteq M_\beta \cap A_\beta.
\]

Let \(B_\beta = \sum_{\alpha \in S, \alpha > \beta} A_\alpha + \sum_{\alpha \in T, \alpha < \beta} A_\alpha\). We will prove that \(A_\beta \cap B_\beta = M_\beta \cap A_\beta\). We have only to show that for each \(v \in V\), \(A_\beta(v) \cap B_\beta(v) \subseteq A_\beta(v) \cap M_\beta(v)\). Let \(a \in A_\beta(v) \cap B_\beta(v)\). Then \(a = e + a_{\alpha_0} + \cdots + a_{\alpha_k}\) where \(e \in \sum_{\alpha \in T, \alpha < \beta} A_\alpha(v) \subseteq M_\beta(v)\), \(\alpha_i \in S\) and \(a_{\alpha_i} \in A_{\alpha_i}(v)\) for all \(i \leq k\) and \(\alpha_i > \alpha_{i+1}\) for all \(i < k\). W.l.o.g., we can assume that \(\alpha_0\) is minimal possible. If \(\alpha_0 > \beta\), then \(a_{\alpha_0} = e - a_{\alpha_0} + \cdots - a_{\alpha_k} \in M_\alpha(v) \cap A_{\alpha_0}(v) \subseteq \sum_{\alpha \in S, \alpha < \alpha_0} A_\alpha(v)\) (since \(\alpha_0 \in S\)), in contradiction with the minimality of \(\alpha_0\). Since \(\beta \not\in S\), we infer that \(a_{\beta < \beta}, a \in M_\beta(v)\), and \(A_\beta \cap B_\beta = A_\beta \cap M_\beta\).

So if \(\beta \in T \setminus S\) then \(\mathcal{F}_{\beta+1}/\mathcal{F}_\beta \cong A_\beta/(M_\beta \cap A_\beta) \cong M_{\beta+1} / M_\beta\), and the latter is isomorphic to an element of \(J\) because \(0 \in J\)-filtration of \(M\). This finishes the proof of condition (3).

For condition (4) we first claim that each subset of \(\sigma\) of cardinality \(<\lambda\) is contained in a closed subset of cardinality \(<\lambda\). Since \(\lambda\) is regular and unions of closed sets are closed, it suffices to prove the claim only for one-element subsets of \(\sigma\). By induction on \(\beta\) we prove that each \(\beta < \sigma\) is contained in a closed set \(S\) of cardinality \(<\lambda\). If \(\beta < \lambda\) we take \(S = \beta + 1\).

Otherwise, consider the short exact sequence \(0 \to M_\beta / A_\beta \to A_\beta \to M_{\beta+1} / M_\beta \to 0\). By our assumption on \(\lambda\), since \(A_\beta\) is locally \(<\lambda\)-presented, so is \(M_\beta \cap A_\beta\). Hence for each \(v \in V\), \(M_\beta(v) \cap A_\beta(v) \subseteq \sum_{\alpha \in S} A_\alpha(v)\) for a subset \(S_v \subseteq \beta\) of cardinality \(<\lambda\). By our inductive premise, the set \(\bigcup_{v \in V} S_v\) is contained in a closed subset \(S'\) of cardinality \(<\lambda\). Let \(S = S' \cup \{\beta\}\). Then \(S\) is closed because \(S'\) is closed, and \(M_\beta \cap A_\beta \subseteq \sum_{\alpha \in S} A_\alpha\).

Finally if \(N = \sum_{\alpha \in S} A_\alpha\) and \(X\) is a locally \(<\lambda\)-presented quasi-coherent subsheaf of \(M\), then \(X \subseteq \sum_{\alpha \in T} A_\alpha\) for a subset \(T\) of \(\sigma\) of cardinality \(<\lambda\). By the above we can assume that \(T\) is closed and put \(P = \sum_{\alpha \in S \cup T} A_\alpha\). By (the proof of) condition
(3) $\mathcal{P}/N$ is $\mathcal{J}$–filtered, and the length of the filtration can be taken $\leq |T \setminus S|$. This implies that $\mathcal{P}/N$ is locally $<\lambda$–presented. \hfill \Box

Our third tool is essentially [8, Proposition 3.3] (where we omit the condition of $\mathcal{M}(v)$ being a pure submodule in $\mathcal{M}(v)$, because we do not need it in the sequel). This tool will be applied to form filtrations of quasi–coherent sheaves by connecting the individual $\mathcal{R}(v)$–module filtrations for all $v \in V$.

**Lemma 3.6.** Let $Q_X = (V, E)$ be a quiver associated to a scheme $X$, and let $M \in \mathfrak{Qco}(X)$. Let $v$ be an infinite cardinal such that $\kappa \geq |V|$, and $\kappa \geq |R(v)|$ for all $v \in V$. Let $\mathcal{M}_v \subseteq \mathcal{M}(v)$ be subsets with $|X_v| \leq \kappa$ for all $v \in V$. Then there is a locally $\leq \kappa$-presented quasi-coherent subsheaf $\mathcal{M}' \subseteq \mathcal{M}$ such that $\mathcal{M}_v \subseteq \mathcal{M}'(v)$ for all $v \in V$

Now we fix our notation:

**Notation 3.7.** Let $Q_X = (V, E)$ be a quiver associated to a scheme $X$, and $\kappa$ be an infinite cardinal such that $\kappa \geq |V|$ and $\kappa \geq |R(v)|$ for all $v \in V$. For each $v \in V$, let $S_v$ be a class of $\leq \kappa$-presented $\mathcal{R}(v)$–modules, $\mathcal{F}_v = \langle S_v \rangle$, $\mathcal{L}$ be the class of all locally $\leq \kappa$-presented quasi–coherent sheaves $N$ such that $N(v) \in \mathcal{F}_v$ for each $v \in V$, and $\mathcal{C}$ be the class of all quasi–coherent sheaves $M$ such that $M(v) \in \mathcal{F}_v$ for each $v \in V$.

**Theorem 3.8.** Each quasi–coherent sheaf $M \in \mathcal{C}$ has an $\mathcal{L}$–filtration.

**Proof.** Let $v \in V$ and put $\lambda = \kappa^+$. Denote by $F^\leq v$ the subclass of $\mathcal{F}_v$ consisting of all $\leq \kappa$-presented modules. By Lemma 3.4, $\mathcal{M}(v)$ has a $F^\leq v$–filtration $\mathcal{M}_v$. Denote by $\mathcal{H}_v$ the family associated to $\mathcal{M}_ IS$ in Lemma 3.3. And let $\{m_{v,\alpha} | \alpha < \tau_v\}$ be an $\mathcal{R}(v)$-generating set of the $\mathcal{R}(v)$-module $\mathcal{M}(v)$. W.l.o.g., we can assume that $\tau = \tau_v$ for all $v \in V$.

We will construct an $\mathcal{L}$–filtration $(\mathcal{M}_\alpha | \alpha \leq \tau)$ of $\mathcal{M}$ by induction on $\alpha$. Let $M_0 = 0$. Assume that $M_\alpha$ is defined for some $\alpha < \tau$ so that $M_\alpha(v) \in \mathcal{H}_v$ and $m_{v,\beta} \in M(v)$ for all $\beta < \alpha$ and all $v \in V$. Set $N_{v,0} = M_\alpha(v)$. By Lemma 3.3,(4), there is a module $N_{v,1} \in \mathcal{H}_v$ such that $N_{v,0} \subseteq N_{v,1}$, $m_{v,\alpha} \in N_{v,1}$ and $N_{v,1}/N_{v,0}$ is $\leq \kappa$-presented.

By Lemma 3.6 (with $M$ replaced by $M/M_\alpha$, and $X_v = N_{v,1}/M_\alpha(v)$) there is a quasi-coherent subsheaf $M'_1$ of $M$ such that $M_\alpha \subseteq M'_1$ and $M'_1/M_\alpha$ is locally $\leq \kappa$-presented. Then $M'_1(v) = N_{v,1} + (T_v)$ for a subset $T_v \subseteq M'_1(v)$ of cardinality $\leq \kappa$, for each $v \in V$.

By Lemma 3.3,(4) there is a module $N_{v,2} \in \mathcal{H}_v$ such that $M'_1(v) = N_{v,1} + (T) \subseteq N_{v,2}$ and $N_{v,2}/N_{v,1}$ is $\leq \kappa$-presented.

Proceeding similarly, we obtain a countable chain $(M'_n | n < \aleph_0)$ of quasi-coherent subsheaves of $M$, as well as a countable chain $(N_{v,n} | n < \aleph_0)$ of $\mathcal{R}(v)$-submodules of $\mathcal{M}(v)$, for each $v \in V$. Let $M_{\alpha+1} = \bigcup_{n<\aleph_0} M'_n$. Then $M_{\alpha+1}$ is a quasi-coherent subsheaf of $M$ satisfying $M_{\alpha+1}(v) = \bigcup_{n<\aleph_0} N_{v,n}$ for each $v \in V$. By Lemma 3.3,(2) and (3) we deduce that $M_{\alpha+1}(v) \in \mathcal{H}_v$ and $M_{\alpha+1}(v)/M_\alpha(v) \in F^\leq v$. Therefore $M_{\alpha+1}/M_\alpha \in \mathcal{L}$.

Assume $M_\beta$ has been defined for all $\beta < \alpha$ where $\alpha$ is a limit ordinal $\leq \tau$. Then we define $M_\alpha = \bigcup_{\beta < \alpha} M_\beta$. Since $m_{v,\alpha} \in M_{\alpha+1}(v)$ for all $v \in V$ and $\alpha < \tau$, we have $M_\tau(v) = M(v)$, so $(M_v | \alpha \leq \tau)$ is an $\mathcal{L}$–filtration of $\mathcal{M}$.

**Remark 3.9.** Recall that a module $N$ is strongly $\leq \kappa$-presented provided that $N$ has a projective resolution consisting of $\leq \kappa$-generated projective modules. If this is the case we will always consider only the projective resolutions of $N$ that consist of $\leq \kappa$-generated modules.

A class of modules $\mathcal{C}$ is syzygy closed if for each $C \in \mathcal{C}$, the first (and hence each) syzygy of $C$ in some projective resolution of $C$ is contained in $\mathcal{C}$. 

We note that Theorem 3.8 remains true under the stronger assumption that for each \( v \in V \), \( S_v \) is a class of strongly \( \leq \kappa \)-presented \( R(v) \)-modules and \( F_v = \perp S_v \).

It is clear that the class \( C \) is closed under extensions, retractions and direct sums. As a consequence of Theorem 3.8 we get the following two corollaries.

**Corollary 3.10.** Let \( X \) be any scheme with associated quiver \( Q_X \). Let \( C \) and \( L \) be the subclasses of \( \Omega_{co}(X) \) defined above. Then \( C = \text{Filt}(L) \).

**Proof.** The inclusion \( C \subseteq \text{Filt}(L) \) follows by Theorem 3.8, and \( \text{Filt}(L) \subseteq \text{Filt}(C) \subseteq C \) by Lemma 3.1 (and Remark 3.2). \( \Box \)

**Corollary 3.11.** Let \( X \) be any scheme with associated quiver \( Q_X \). Let \( C \) and \( L \) be the subclasses of \( \Omega_{co}(X) \) defined above. Suppose that \( C \) contains a generator of \( \Omega_{co}(X) \). Then \( (\perp C, \perp L) \) is a complete cotorsion pair.

**Proof.** Since \( L \subseteq \perp (L^+) \), we have \( \text{Filt}(L) \subseteq \text{Filt} (\perp (L^+)) \). By Lemma 3.1, \( \text{Filt}(\perp (L^+)) = \perp (L^+) \). So by Corollary 3.10, \( C \subseteq \perp (L^+) \).

In order to prove that \( (C, L^+) \) is a complete cotorsion pair, we first show that \( \perp (L^+) \subseteq C \). By [11, Lemma 2.4, Theorem 2.5], for all \( Q \in \Omega_{co}(X) \) there exists a short exact sequence

\[
0 \to Q \to P \to Z \to 0
\]

where \( P \in L^+ \) and \( Z \) has an \( L \)-filtration. Given any \( M \in \Omega_{co}(X) \), since the generator \( G \) of \( \Omega_{co}(X) \) is in \( C \), there exists a short exact sequence

\[
0 \to U \to G' \to M \to 0
\]

where \( G' \) is a direct sum of copies of \( G \in L \). Now let

\[
0 \to U \to N \to Z \to 0
\]

be exact with \( N \in L^+ \) and \( Z \) admitting an \( L \)-filtration. Form a pushout and get

\[
\begin{array}{ccccccccc}
0 & 0 \\
\downarrow & & \\
0 & \longrightarrow & U & \longrightarrow & G' & \longrightarrow & M & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \| & & \\
0 & \longrightarrow & N & \longrightarrow & W & \longrightarrow & M & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \\
Z & \longrightarrow & Z & \longrightarrow & \\
\downarrow & & \downarrow & & \\
0 & 0 & & & & & & & & \\
\end{array}
\]

Then since \( G' \) is a direct sum of copies of \( G \in C \) and \( Z \) has an \( L \)-filtration (so \( Z \in C \) by Corollary 3.10), we see that \( W \in C \). Also \( N \in L^+ \). Hence if \( M \in \perp (L^+) \) we get that \( 0 \to N \to W \to M \to 0 \) splits and so \( M \) is a direct summand of \( W \in C \). But then \( M \in C \) because \( C \) is closed under direct summands.

This proves that \( C = \perp (L^+) \). Moreover (1) shows that the cotorsion pair \( (C, L^+) \) has enough injectives, and the second line of the diagram above that it has enough projectives. \( \Box \)

Focussing on particular classes of modules, we obtain several interesting corollaries of Theorem 3.8:
Corollary 3.12 (Kaplansky Theorem for vector bundles). Let $X$ be a scheme and $\kappa$ an infinite cardinal such that $\kappa \geq |V|$ and $\kappa \geq |\mathcal{R}(v)|$ for all $v \in V$. Then every vector bundle on $X$ has an $\mathcal{L}$-filtration where $\mathcal{L}$ is the class of all locally $\kappa$-presented vector bundles.

In particular, if $X$ is a scheme, $Q_X = (V, E)$ is a quiver associated to $X$, and both $V$ and all the rings $\mathcal{R}(v)$ ($v \in V$) are countable, then every vector bundle on $X$ has a filtration by locally countably generated vector bundles.

Proof. This follows by taking $S_v = \{\mathcal{R}(v)\}$ (so $\mathcal{F}_v$ is the class of all projective $\mathcal{R}(v)$-modules) for all $v \in V$, and then applying Theorem 3.8. □

Let $\kappa$ be an infinite cardinal such that $\kappa \geq |V|$ and $\kappa \geq |\mathcal{R}(v)|$ for all $v \in V$. For the next corollary, we fix $\mathcal{C}$ to be the class of quasi-coherent sheaves $\mathcal{M}$ such that each $\mathcal{M}(v)$ has a filtration by $\leq \kappa$-presented flat Mittag–Leffler modules.

Corollary 3.13. Let $X$ be a scheme, $\kappa$ an infinite cardinal such that $\kappa \geq |V|$ and $\kappa \geq |\mathcal{R}(v)|$ for all $v \in V$. Let $\mathcal{L}$ be the class of locally $\leq \kappa$-presented Drinfeld vector bundles. For each $v \in V$, let $S_v$ denote the class of all $\leq \kappa$-presented flat Mittag–Leffler modules. Let $\mathcal{F}_v$ and $\mathcal{C}$ be defined as before Corollary 3.10. Then $\text{Filt}(\mathcal{L}) = \mathcal{C}$.

In 5.7, we will see that in general Corollary 3.13 fails for arbitrary Drinfeld vector bundles. Our final application goes back to [8, Section 4]:

Corollary 3.14. Let $X$ be a scheme. Let $\kappa$ be an infinite cardinal such that $\kappa \geq |V|$ and $\kappa \geq |\mathcal{R}(v)|$ for all $v \in V$.

Then every flat quasi-coherent sheaf on $X$ has an $\mathcal{L}$-filtration where $\mathcal{L}$ is the class of all locally $\leq \kappa$-presented flat quasi-coherent sheaves.

Proof. For each vertex $v \in V$, we take a set $S_v$ of representatives of iso classes of flat $\mathcal{R}(v)$-modules of cardinality $\leq \kappa$. Then by Lemma 3.1 and [1, Lemma 1] it follows that $\mathcal{F}_v = \{S_v^1\}$ is the class of all flat $\mathcal{R}(v)$-modules. Finally, we apply Theorem 3.8. □

4. Quillen Model Category Structures on $\mathbb{C}(\mathcal{Qco}(X))$.

In this section we develop a method for constructing a model structure on $\mathbb{C}(\mathcal{Qco}(X))$ starting from a priori given sets of modules over sections of the structure sheaf associated to $X$. Our main tool will be Hovey’s Theorem relating cotorsion pairs to model category structures (see [20, Theorem 2.2]).

We recall some standard definitions concerning complexes of objects in a Grothendieck category $\mathcal{A}$. Let $(M, \delta)$ (or just $M$, for simplicity) denote a chain complex in $\mathcal{A}$.

$$\cdots \rightarrow M^{-1} \xrightarrow{\delta^{-1}} M^0 \xrightarrow{\delta^0} M^1 \xrightarrow{\delta^1} \cdots$$

We write $Z(M) = \cdots \rightarrow Z_nM \rightarrow Z_{n+1}M \rightarrow \cdots$ and $B(M) = \cdots \rightarrow B_nM \rightarrow B_{n+1}M \rightarrow \cdots$ for the subcomplexes consisting of the cycles and the boundaries of $M$.

Given an $M$ in $\mathcal{A}$, let $S^n(M)$ denote the complex which has $M$ in the $(-n)$th position and 0 elsewhere ($n \in \mathbb{Z}$). We denote by $D^n(M)$ the complex $\cdots \rightarrow 0 \rightarrow M \xrightarrow{id} M \rightarrow 0 \rightarrow \cdots$ where $M$ is in the $(-(n+1))$th and $(-n)$th positions ($n \in \mathbb{Z}$).

If $(M, \delta_M)$ and $(N, \delta_N)$ are two chain complexes, we define $	ext{Hom}(M, N)$ as the complex

$$\cdots \rightarrow \prod_{k \in \mathbb{Z}} \text{Hom}(M^k, N^{k+n}) \xrightarrow{\delta^n} \prod_{k \in \mathbb{Z}} \text{Hom}(M^{k}, N^{k+n+1}) \rightarrow \cdots,$$
Then (I) First, consider the particular case of $n$ complexes of objects in $A$. $A$ complex is a dg-structure on $Y$ locally $\leq X$. Then an exact complex $M$ such that $\kappa \geq|\delta^n|$, $\delta^n$ is locally $\kappa$-quasi-coherent on $M$. Let $\mathcal{C}$ denote the class of all $\mathcal{C}$-complexes. Then a complex $M = (M^n)$ in $\mathcal{C}$ is a dg-$\mathcal{C}$ complex if $\text{Hom}(M, E)$ is an exact complex of abelian groups for any complex $E \in C$ and $M^n \in \mathcal{C}$, for each $n \in \mathbb{Z}$. Let $dg \mathcal{C}$ denote the class of all dg-$\mathcal{C}$ complexes of objects in $A$.

Dually we can define the classes $\tilde{\mathcal{C}}$ and $dg \mathcal{C}^\perp$ of $\mathcal{C}$-complexes and dg-$\mathcal{C}^\perp$ complexes of objects in $A$.

We will need the following lemma.

**Lemma 4.1.** Let $X$ be a scheme and $\kappa$ be a regular infinite cardinal such that $\kappa \geq |V|$ and $\kappa \geq |\mathcal{A}(v)|$ for all $v \in V$. Let $N = (N^n), M = (M^n)$ be exact complexes of quasi-coherent sheaves on $X$ such that $N \leq M$. For each $n \in \mathbb{Z}$, let $X_n$ be a locally $\leq \kappa$-presented quasi-coherent subsheaf of $M^n$. Then there exists an exact complex of quasi-coherent sheaves $\mathcal{F} = (\mathcal{F}^n)$ such that $N \leq \mathcal{F} \leq M$, and for each $n \in \mathbb{Z}$, $\mathcal{F}^n \geq N^n + X_n$, and the quasi-coherent sheaf $\mathcal{F}^n/N^n$ is locally $\leq \kappa$-presented.

**Proof.** (I) First, consider the particular case of $N = 0$. Let $Y_0^n = X_n + \delta^{n-1} (X_{n-1})$. Then $(Y_0^n)$ is a subcomplex of $M$.

If $i < \omega$ and $Y^n = \text{Proj}(\mathcal{F}^n)$ is a locally $\leq \kappa$-presented quasi-coherent subsheaf of $M^n$, put $Y^n = Y^n + D^n + \delta^{n-1} (D^{n-1})$, where $D^n$ is a locally $\leq \kappa$-presented quasi-coherent subsheaf of $M^n$ such that $\delta^n(D^n) \geq Z_{n+1} \cap Y^n$. (Such $D^n$ exists by our assumption on $\kappa$, since $Z_{n+1} \cap Y^n \subseteq \text{Ker}(\delta^{n+1}) = \text{Im}(\delta^n).$) Let $\mathcal{F} = \bigcup_{i < \omega} Y^n$. Then $Z_{n+1} \cap \mathcal{F}^{n+1} = \bigcup_{i < \omega} (Z_{n+1} \cap Y^{n+1}) \subseteq \bigcup_{i < \omega} \delta^n(Y^{n+1}) \subseteq \delta^n(\mathcal{F}^n)$. It follows that $\mathcal{F} = (\mathcal{F}^n)$ is an exact subcomplex of $M$. By our assumption on $\kappa$, $\mathcal{F}^n$ is locally $\leq \kappa$-presented.

(II) In general, let $\mathcal{M} = M/N$ and $X_n = (X_n + N^n)/N^n$. By part (I), there is an exact complex of quasi-coherent sheaves $\mathcal{F}$ such that $\mathcal{F} \subseteq \mathcal{M}$, and for each $n \in \mathbb{Z}$, $\mathcal{F}^n \geq X_n$, and the quasi-coherent sheaf $\mathcal{F}^n$ is locally $\leq \kappa$-presented. Then $\mathcal{F} = (\mathcal{F}^n/\mathcal{F}^n)$ for an exact subcomplex $N \leq \mathcal{F} \leq \mathcal{M}$, and $\mathcal{F}$ clearly has the required properties. $\square$

As mentioned above, we will apply [20, Theorem 2.2] to get a model structure on $\mathcal{C}(\mathcal{Qco}(X))$. We point out that $\mathcal{Qco}(X)$ is a closed symmetric monoidal category under the tensor product (in the sense of [21, Section 4.1]) and hence $\mathcal{C}(\mathcal{Qco}(X))$ is also closed symmetric monoidal. We will therefore investigate when the model structure is compatible with the induced closed symmetric monoidal structure.

Let $X$ be a scheme with an associated quiver $Q_X$ (see Section 3). Let $\kappa \geq |V|$, and $\kappa \geq |\mathcal{A}(v)|$ for each $v \in V$. We will assume that $X$ is semi-separated, that is the intersection of two affine open subsets of $X$ is again affine.

For the rest of this section, we fix our notation as in Notation 3.7 and let $\lambda = \kappa^+$. We will moreover assume that $\mathcal{C}$ contains a generator of $\mathcal{Qco}(X)$. Then, by Corollary 3.11, $(\mathcal{C}, L^\perp)$ is a cotorsion pair.

**Lemma 4.2.** $(\mathcal{C}, dg L^\perp)$ is a complete cotorsion pair in $\mathcal{C}(\mathcal{Qco}(X))$.

**Proof.** $(\mathcal{C}, dg L^\perp)$ is a cotorsion pair by [13, Corollary 3.8].

We will prove that each complex $C \in \mathcal{C}$ is $L^\perp$-filtered. Then the completeness of $(\mathcal{C}, dg L^\perp)$ follows as in the proof of Corollary 3.11 because $\mathcal{C}$ contains a generating
set of $C(\mathcal{Qco}(X))$ (for example $D^b(G) \mid n \in \mathbb{Z}$) where $G \in \mathcal{C}$ is a generator of $\mathcal{Qco}(X)$.

Let $\mathcal{C} = (\mathcal{M}^n) \in \mathcal{C}$. Then for each $n \in \mathbb{Z}$, $Z_n \mathcal{C} \in \mathcal{C}$ and therefore $Z_n \mathcal{C}$ has an $\mathcal{L}$-filtration $\mathcal{O}_n = (\mathcal{M}_n^n \mid \alpha \leq \sigma_n)$. For each $n \in \mathbb{Z}$, $\alpha < \sigma_n$, consider a locally $\leq \kappa$-presented quasi-coherent sheaf $A_n^n$ such that $\mathcal{M}_{\sigma_n+1} = \mathcal{M}_n^n + A_n^n$, and the corresponding family $\mathcal{H}_n$ as in Lemma 3.5. Since the complex $\mathcal{C}$ is exact, the $\mathcal{L}$-filtration $\mathcal{O}_{n+1}$ determines a canonical prolongation of $\mathcal{O}_n$ into a filtration $\mathcal{O}'_n = (\mathcal{M}_n^n \mid \alpha \leq \tau_n)$ of $\mathcal{M}^n$ where $\tau_n = \sigma_n + \tau_{n+1}$ (the ordinal sum).

By definition, for each $\alpha \leq \sigma_{n+1}$, $\delta^n$ maps $\mathcal{M}^n_{\sigma_{n+1}}$ onto $\mathcal{M}^n_{\sigma_{n+1}+1}$. So for each $\alpha < \sigma_{n+1}$ there is a locally $\leq \kappa$-presented quasi-coherent subsheaf $A_{n+1}^\sigma$ of $\mathcal{M}_{\sigma_{n+1}+1}$ such that $\delta^n(A_{n+1}^\sigma) = A_{n+1}^\sigma$. Since for each $\sigma_n \leq \alpha < \tau_n$ we have $\ker(\delta^n) \subseteq \mathcal{M}^n_{\sigma_n}$, it follows that $\mathcal{M}^n_{\sigma_{n+1}} = \mathcal{M}^n_{\sigma_n} + A_{n+1}^\sigma$.

Let $\mathcal{H}_n$ be the family corresponding to $A_{n+1}^\sigma (\alpha < \tau_n)$ by Lemma 3.5. Since each closed subset of $\sigma_n$ is also closed when considered as a subset of $\tau_n$, we have $\mathcal{H}_n \subseteq \mathcal{H}'_n$. Note that $\mathcal{Filt}(\mathcal{L}) \subseteq \mathcal{C}$, so $\mathcal{H}_n \subseteq \mathcal{C}$ by condition (3) of Lemma 3.5.

Notice that $Z_n \mathcal{C} = \mathcal{M}_{\sigma_n}^n = \sum_{\alpha < \sigma_n} A_{n+\alpha}^\sigma$. We claim that for each closed subset $S \subseteq \tau_n$, we have $Z_n \mathcal{C} \cap \sum_{\alpha \in S} A_{\sigma_n}^\alpha = \sum_{\alpha \in S \cap \sigma_n} A_{n+\alpha}^\alpha \subseteq \mathcal{H}_n$. To see this, we first show that $\sum_{\alpha \in S} A_{\sigma_n}^\alpha(v) \cap \sum_{\alpha \in S} A_{\sigma_n}^\alpha(v) = \sum_{\alpha \in S \cap \sigma_n} A_{n+\alpha}^\alpha(v)$ for each $v \in V$. The inclusion $\subseteq$ is clear, so consider $a \in (\sum_{\alpha \in S} A_{\sigma_n}^\alpha(v)) \cap (\sum_{\alpha \in S} A_{\sigma_n}^\alpha(v))$. Then $a = a_{\sigma_n} + \cdots + a_{\sigma_n}$, where $a_{\sigma_n} \in S$, $a_{\sigma_n} = A_{\sigma_n}^\alpha(v)$ for all $i \leq k$, and $\alpha_i > \alpha_{i+1}$ for all $i < k$. W.l.o.g., we can assume that $\alpha_0$ is minimal possible. Since $\sigma_n \geq \alpha_0$, then $a_{\sigma_n} = a_{\sigma_n} - \cdots - a_{\sigma_n} \in \sum_{\alpha < \sigma_n} A_{\sigma_n}^\alpha(v)$ for all $i \leq k$, and $\alpha_i > \alpha_{i+1}$ for all $i < k$. Since $\mathcal{C}$ is closed in $\mathcal{M}^n_{\sigma_n}$, and therefore $\mathcal{M}^n_{\sigma_n} \subseteq \mathcal{H}_n$, and the latter quasi-coherent sheaf is in $\mathcal{H}_n$, because $S \cap \sigma_n$ is closed in $\sigma_n$. This proves our claim.

By induction on $\alpha$, we will construct an $\mathcal{L}$-filtration $(\mathcal{C}_n \mid \alpha \leq \sigma)$ of $\mathcal{C}$ such that $\mathcal{C}_n = (\mathcal{N}^n_{\sigma_n})$, $Z_n \mathcal{C}_n \subseteq \mathcal{H}_n$ and $\mathcal{N}^n_{\sigma_n} \subseteq \mathcal{H}'_n$ for each $n \in \mathbb{Z}$.

First, $\mathcal{C}_0 = 0$, and if $\mathcal{C}_\alpha$ is defined and $\mathcal{C}_\alpha \neq \mathcal{C}$, then for each $n \in \mathbb{Z}$ we take a locally $\leq \kappa$-presented quasi-coherent sheaf $\mathcal{X}_\alpha$ such that $\mathcal{X}_\alpha \not\subseteq \mathcal{N}^n_{\sigma_n}$ in case $\mathcal{N}^n_{\sigma_n} \not\subseteq \mathcal{M}^n$ (this is possible by our assumption on $\kappa$), or $\mathcal{X}_\alpha = 0$ if $\mathcal{M}^n = \mathcal{N}^n_{\sigma_n}$. If $\mathcal{M}^n = \mathcal{N}^n_{\sigma_n}$ for each $n \in \mathbb{Z}$, we set $\sigma = \alpha$ and finish our construction.

By Lemma 4.1 there exists an exact subcomplex $\mathcal{T} = (\mathcal{T}^n)$ of $\mathcal{C}$ containing $\mathcal{C}_\alpha$ such that for each $n \in \mathbb{Z}$, $\mathcal{T}^n \supseteq \mathcal{N}^n_{\sigma_n} + \mathcal{X}_\alpha$, and the quasi-coherent sheaf $\mathcal{T}^n/\mathcal{N}^n_{\sigma_n}$ is locally $\leq \kappa$-presented. Then $\mathcal{Y}_n = \mathcal{T}^n - \mathcal{N}^n_{\sigma_n} + \mathcal{X}_\alpha$ for a locally $\leq \kappa$-presented quasi-coherent subsheaf $\mathcal{Y}_n$ of $\mathcal{M}^n$. By condition (4) of Lemma 3.5 (for $\mathcal{N} = \mathcal{N}^n_{\sigma_n}$ and $\mathcal{X} = \mathcal{X}_\alpha$), there exists a quasi-coherent sheaf $\mathcal{Y}_n = \mathcal{F}^n$ in $\mathcal{H}_n$ such that $\mathcal{N}^n_{\sigma_n} + \mathcal{Y}_n = \mathcal{T}^n \subseteq \mathcal{F}^n$ and $\mathcal{F}^n/\mathcal{N}^n_{\sigma_n}$ is locally $\leq \kappa$-presented. Iterating this process we obtain a countable chain $\mathcal{Y}_n \subseteq \mathcal{Y}_n \subseteq \cdots \subseteq \mathcal{Y}_n$, whose union $\mathcal{N}^n_{\sigma_n+1} \subseteq \mathcal{H}'_n$ by condition (2) of Lemma 3.5. Then $\mathcal{C}_{\sigma_n+1} = (\mathcal{N}^n_{\sigma_n+1})$ is an exact subcomplex of $\mathcal{C}$ containing $\mathcal{C}_\alpha$. Since $\mathcal{N}^n_{\sigma_n+1} \subseteq \mathcal{H}'_n$, we have $Z_n \mathcal{C}_{\sigma_n+1} = Z_n \mathcal{C} \cap \mathcal{N}^n_{\sigma_n+1} \subseteq \mathcal{H}_n$ by the claim above.

In order to prove that $Z_n \mathcal{C}_{\sigma_n+1} \subseteq \mathcal{C}$, it remains to show that for each $n \in \mathbb{Z}$, $Z_n \mathcal{C}_{\sigma_n+1} \subseteq \mathcal{C}_n$. Since the complex $\mathcal{C}_{\sigma_n+1}/\mathcal{C}_n$ is exact, it suffices to prove that $F(\delta^n(\mathcal{N}^n_{\sigma_n+1}) + \mathcal{N}^n_{\sigma_n+1})/\mathcal{C}_n \subseteq \mathcal{C}$.

We have $\mathcal{N}^n_{\sigma_n+1} = \sum_{\alpha \in S} A_{\sigma_n+\alpha}$ where w.l.o.g., $S$ is a closed subset of $\tau_n$ containing $\sigma_n$. Let $S' = \{ \alpha < \sigma_{n+1} \mid \sigma_n + \alpha \in S \}$. Then $S'$ is a closed subset on $\tau_{n+1} = \sigma_{n+1}+1$. Indeed, for each $\alpha \in S'$, we have

$$\sum_{\beta < \alpha} A_{\beta+1}^\sigma \cap A_{\alpha}^\sigma = \delta^n(\sum_{\beta < \sigma_{n+1}} A_{\beta+1}^\sigma) \cap A_{\sigma_{n}+\alpha} \subseteq \delta^n(\sum_{\beta < \sigma_{n+1}, \beta \in S} A_{\beta+1}^\sigma) = \sum_{\beta < \sigma_{n+1}, \beta \in S} A_{\beta+1}^\sigma$$

where the inclusion $\subseteq$ holds because $S$ is closed in $\tau_n$ and $\ker(\delta^n) \subseteq \sum_{\beta < \sigma_{n+1}} A_{\beta+1}^\sigma$. 

MODEL CATEGORY STRUCTURES ARISING FROM DRINFELD VECTOR BUNDLES 11
Since $\delta^n(N^\alpha_{n+1}) = \sum_{\beta \in S'} A^{n+1}_\beta$, and $N^\alpha_{n+1} = \sum_{\beta \in \mathcal{T}} A^{n+1}_\beta$ for a closed subset $T$ of $\tau_{n+1}$, we have $F = \sum_{\beta \in S' \cup T} A^{n+1}_\beta / \sum_{\beta \in \mathcal{T}} A^{n+1}_\beta$, so $F \in \mathcal{C}$ by condition (3) of Lemma 3.5 for $\mathcal{H}_{n+1}$. This finishes the proof of $\mathcal{C}_\alpha \to \mathcal{C}_\alpha \in \widetilde{\mathcal{L}}$.

If $\alpha$ is a limit ordinal we define $\mathcal{C}_\alpha = \bigcup_{\delta < \alpha} \mathcal{C}_\delta = (N^\alpha_\alpha)$. Then $N^\alpha_\alpha \in \mathcal{H}^\alpha_n$ by condition (2) of Lemma 3.5, and $Z_n \mathcal{C}_\alpha = Z_n \mathcal{C} \cap N^\alpha_\alpha \in \mathcal{H}^\alpha_n$ by the claim above. This finishes the construction of the $\mathcal{L}$–filtration of $\mathcal{C}$.

Following [20, Definition 6.4], we call a cotorsion pair $(\mathcal{F}, \mathcal{C})$ in an abelian category $\mathcal{A}$ small provided that $(A1)$ $\mathcal{F}$ contains a generator of $\mathcal{A}$, $(A2)$ $\mathcal{C} = S^\perp$ for a subset $S \subseteq \mathcal{F}$, and $(A3)$ for each $S \in \mathcal{S}$ there is a monomorphism $i_S$ with cokernel $S$ such that if $A(i_S, X)$ is surjective for all $S \in \mathcal{S}$, then $X \in \mathcal{C}$.

We now show that condition $(A3)$ above is redundant in case $\mathcal{A}$ is a Grothendieck category:

**Lemma 4.3.** Let $(\mathcal{F}, \mathcal{C})$ be a cotorsion pair in a Grothendieck category $\mathcal{A}$ satisfying conditions $(A1)$ and $(A2)$ above. Then $(\mathcal{F}, \mathcal{C})$ is small.

**Proof.** We will show that $(\mathcal{F}, \mathcal{C})$ satisfies a slightly weaker version of condition $(A3)$, namely that for each $L \in \mathcal{S}$ there is a set $\mathcal{E}_L$ of exact sequences $0 \to K \to U \to L \to 0$ such that $Y \in \mathcal{C}$ if and only if $\text{Hom}(U, Y) \to \text{Hom}(K, Y) \to 0$ is exact for each exact sequence in $\mathcal{E}_L$. For a given $L$, we define $\mathcal{E}_L$ as the set of all representatives of short exact sequences $0 \to K \to U \to L \to 0$ where $U$ is $\leq \kappa$–presented (where $\kappa$ comes from [9, Corollary 2.3] for $Y = L$; in particular, we can take $\kappa$ as in Notation 3.7 in case $\mathcal{A} = \mathcal{C}(\text{Qco}(X))$).

Suppose that $G$ is an object of $\mathcal{A}$ such that $\text{Hom}(U, G) \to \text{Hom}(K, G) \to 0$ is exact for each exact sequence in $\mathcal{E}_L$. We will prove that $\text{Ext}^1(L, G) = 0$ for all $L \in \mathcal{F}$. By condition $(A2)$, it suffices to prove that $\text{Ext}^1(L, G) = 0$ for all $L \in \mathcal{S}$. So let $0 \to G \to V \to L \to 0$ be exact with $L \in \mathcal{S}$. We want to show that this sequence splits. By our choice of $\kappa$, there is $U \subseteq V$ such that $U$ is $\leq \kappa$–presented and $V = G + U$. Then the sequence $0 \to G \cap U \to U \to L \to 0$ is isomorphic to one in $\mathcal{E}_L$.

Consider the commutative diagram

\[
\begin{array}{ccccccccc}
0 & \to & G \cap U & \to & U & \to & L & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & G & \to & G + U & \to & L & \to & 0.
\end{array}
\]

Our hypothesis now implies that the inclusion $G \cap U \to G$ can be extended to $U \to G$ so, since the left–hand square is a pushout, we see that the bottom row splits. This proves that $\text{Ext}^1(L, G) = 0$. Now, replacing the set $\mathcal{S}$ by $\mathcal{S}' = \{L \text{card} (\mathcal{E}_L) \mid L \in \mathcal{S}\}$, we see that both conditions $(A2)$ and $(A3)$ hold for $\mathcal{S}'$, hence the cotorsion pair $(\mathcal{F}, \mathcal{C})$ is small.

Now we can prove the main theorem of our paper.

**Theorem 4.4.** Let $X$ be a semi-separated scheme. There is a model category structure on $\mathcal{C}(\text{Qco}(X))$ where the weak equivalences are the homology isomorphisms, the cofibrations (resp. trivial cofibrations) are the monomorphisms with cokernels in $\text{dg} \mathcal{F}$ (resp. in $\mathcal{C}$), and the fibrations (resp. trivial fibrations) are the epimorphisms whose kernels are in $\text{dg} \mathcal{L}^\perp$ (resp. $\mathcal{C}^\perp$).

Moreover, if every $M \in \mathcal{S}_v$ is a flat $\mathcal{R}(v)$–module, and $M \otimes_{\mathcal{R}(v)} N \in \mathcal{S}_v$ whenever $M, N \in \mathcal{S}_v$, then the model structure is monoidal with respect to the usual tensor product of complexes of quasi-coherent sheaves.
Proof. We will apply Hovey’s Theorem [20, Theorem 2.2]. First, the results of [20, Section 5] guarantee that the weak equivalences of our model structure are the homology isomorphisms. In our case \( W \) is the class of all exact complexes of quasi-coherent sheaves. It is easy to check that this is a thick subcategory of \( \mathcal{C}(\mathcal{Qco}(X)) \). Now, according to Hovey’s Theorem, we will have to check that the pairs \((dg\tilde{C}, dg\mathcal{L}^+ \cap W)\) and \((dg\tilde{C} \cap W, dg\tilde{L}^+)\) are complete cotorsion pairs (notice that our notion of completeness coincides with Hovey’s notion of ‘functorial completeness’). We will proceed in three steps, proving that

1. The pairs \((\tilde{C}, dg\mathcal{L}^+)\) and \((dg\tilde{C}, \mathcal{L}^+)\) are cotorsion pairs.
2. \(dg\tilde{C} \cap W = \tilde{C}\) and \(dg\mathcal{L}^+ \cap W = \mathcal{L}^+\).
3. The cotorsion pairs \((\tilde{C}, dg\mathcal{L}^+)\) and \((dg\tilde{C}, \mathcal{L}^+)\) are complete.

Condition (1) follows from [13, Corollary 3.8].

Let us check condition (2). By [14, Corollary 3.9] (4. \( \Rightarrow 1.\)) it suffices to prove that \(dg\tilde{C} \cap W = \tilde{C}\). The inclusion \( \tilde{C} \subseteq dg\tilde{C} \cap W \) was proven in [13, Lemma 3.10]. Let us prove that \(dg\tilde{C} \cap W \subseteq \tilde{C}\). So let \( Y \) be a complex in \( dg\tilde{C} \cap W \) (so \( Y(v) \) is a complex of \( \mathcal{R}(v)\)-modules, for all \( v \in V \)). To see that \( Y \) is in \( \tilde{C} \) we have to check that \( Z_n Y \in \mathcal{C} \), for all \( n \in \mathbb{Z} \). But this means that the \( \mathcal{R}(v)\)-module \( Z_n Y(v) \) belongs to \( F_v \) for all \( v \in V \). By [14, Corollary 3.9] if a complex of \( \mathcal{R}(v)\)-modules is exact and belongs to \( dg\mathcal{F}_v \) then it belongs to \( \mathcal{F}_v \) (so \( Z_n Y(v) \in F_v \) for all \( v \in V \)). Therefore we will be done if we prove that \( Y(v) \) is exact and belongs to \( dg\mathcal{F}_v \). Since the complex \( Y \) is exact, for each affine open set \( v \in V \), \( Y(v) \) is an exact complex of \( \mathcal{R}(v)\)-modules. Let us see that \( Y(v) \in dg\mathcal{F}_v \), for all \( v \in V \). So let \( E \) be a complex of \( \mathcal{R}(v)\)-modules in \( \mathcal{S}_v^{-} \) (so \( E \) is exact and \( Z_n E \in \mathcal{S}_v^{-} \)). We have to check that \( Hom(Y(v), E) \) is exact. Since \( X \) is semi-separated, by [19, Proposition 5.8] there exists a right adjoint \( i_*: \mathcal{R}(v)-\text{Mod} \to \mathcal{Qco}(X) \) of the restriction functor \( i^*: \mathcal{Qco}(X) \to \mathcal{R}(v)-\text{Mod} \) (defined by \( i^*(M) = M(v) \)). The adjointness situation can be lifted up to \( \mathcal{C}(\mathcal{Qco}(X)) \). Then there is an isomorphism

\[
\text{Hom}_{\mathcal{C}(\mathcal{Qco}(X))}(Y(v), E) = \text{Hom}_{\mathcal{C}(\mathcal{R}(v))}(i^*(v)(M), E) \cong \text{Hom}_{\mathcal{C}(\mathcal{Qco}(X))}(Y, i_*v(E))
\]

and since the functor \( i_*v \) preserves exactness, \( i_*v(E) \) will be an exact complex in \( \mathcal{C}(\mathcal{Qco}(X)) \). Since \( Y(v) \in dg\tilde{C} \), once we show that \( i_*v(E) \in \mathcal{L}^+ \) we will finish by the comment above. But, \( Z_n i_*v(E) = i_*v(Z_n E) \). Hence, for each \( T \in \mathcal{C} \),

\[
\text{Ext}^1_{\mathcal{Qco}(X)}(T, i_*v(Z_n E)) \cong \text{Ext}^1_{\mathcal{R}(v)}(i^*(v)(T), Z_n E) = 0,
\]

where the last equality follows because \( i^*(v)(T) = T(v) \in F_v \) and \( Z_n E \in \mathcal{S}_v^{-} \).

Now let us prove condition (3). By Lemma 4.2 the cotorsion pair \((\tilde{C}, dg\mathcal{L}^+)\) is complete. We claim that the cotorsion pair \((dg\tilde{C}, \mathcal{L}^+)\) is also complete. Let \( \mathcal{T}' \) be a set of representatives of the quasi-coherent sheaves in \( \mathcal{L} \). Then clearly \( (\mathcal{T}')^+ = \mathcal{L}^+ \).

We will prove that \( \mathcal{T}^+ = \mathcal{L}^+ \) where \( \mathcal{T} = \{ S^m(A) \mid A \in \mathcal{T}', n \in \mathbb{Z} \} \cup \{ S^m(\mathcal{G}) \mid n \in \mathbb{Z} \} \) (and \( \mathcal{G} \in \mathcal{C} \) is a generator of \( \mathcal{Qco}(X) \)). Then the claim will follow by Lemma 4.3 and [20, Corollary 6.6]. It is easy to check that \( \mathcal{T} \subseteq dg\tilde{C} \) for \( S^m(A)^l \in \mathcal{C} \) \( (l \in \mathbb{Z}) \), and for every exact complex \( M \in \mathcal{L}^+ \), \( \text{Hom}(S^m(A), M) \) is the complex

\[
\cdots \to \text{Hom}(A, M^l) \to \text{Hom}(A, M^{l+1}) \to \cdots
\]

which is obviously exact because \( Z_n M, B_n M \in \mathcal{L}^+ \). Therefore \( \mathcal{T}^+ \supseteq (dg\tilde{C})^+ = \mathcal{L}^+ \).

We now prove the converse: let \( N \in \mathcal{T}^+ \). We have to see that \( N \) is exact and that \( Z_n N \in \mathcal{L}^+ \). First, we prove that \( N \) is exact. It is clear that this is equivalent
to each morphism $S^n(\mathcal{M}) \to \mathcal{N}$ (for $\mathcal{M}$ a generator of $\mathcal{Qco}(X)$) being extendable to $D^n(\mathcal{M}) \to \mathcal{N}$ for each $n \in \mathbb{Z}$. But this follows from the short exact sequence

$$0 \to S^n(\mathcal{M}) \to D^n(\mathcal{M}) \to S^{n+1}(\mathcal{M}) \to 0$$

since $\text{Ext}^1(S^{n+1}(\mathcal{M}), \mathcal{N}) = 0$. Now we prove that $Z_n \mathcal{N} \in \mathcal{L}^\perp$. Since $\mathcal{L}^\perp = \mathcal{L}^\perp$ we only need to prove that $\text{Ext}^1_{\mathcal{Qco}(X)}(\mathcal{A}, Z_n \mathcal{N}) = 0$ for all $n \in \mathbb{Z}$. But there exists a monomorphism of abelian groups

$$0 \to \text{Ext}^1_{\mathcal{Qco}(X)}(\mathcal{A}, Z_n \mathcal{N}) \to \text{Ext}^1_{\mathcal{Qco}(X)}(S^{-n}(\mathcal{A}), \mathcal{N})$$

(see e.g. [10, Lemma 5.1]) and since the latter group is 0, we get that $Z_n \mathcal{N} \in \mathcal{L}^\perp$. This proves our claim, and thus finishes the proof of condition (3).

Finally to get that the model structure is monoidal we apply [14, Theorem 5.1] (by noticing that the argument of the proof of [14, Theorem 5.1] carries over without the assumption of $\mathcal{F}$ being closed under direct limits). If $\mathcal{S}_v$ is contained in the class of all flat modules then every quasi-coherent sheaf in $\mathcal{C}$ is flat. So condition (1) of [14, Theorem 5.1] holds. Now if $M \otimes_{\mathcal{R}(v)} N \in \mathcal{S}_v$, where $M, N \in \mathcal{R}(v)$-modules in $\mathcal{S}_v$, it follows that $L \otimes_{\mathcal{R}(v)} T \in \mathcal{F}_v$, where $L, T \in \mathcal{S}_v$-filtered $\mathcal{R}(v)$-modules (because the tensor product commutes with direct limits). And so $L \otimes_{\mathcal{R}} \mathcal{F} \subset \mathcal{C}$, for any $L, \mathcal{F} \in \mathcal{C}$. So condition (2) of [14, Theorem 5.1] also holds. Finally condition (3) of [14, Theorem 5.1] is immediate because, for all $v \in V$, $\mathcal{F}_v$ contains all projective $\mathcal{R}(v)$-modules, so in particular $\mathcal{R} \in \mathcal{C}$. □

The proof of Corollaries 1.2 and 1.3. In Theorem 4.4, we take $\mathcal{S}_v = \{R(v)\}$, and $\mathcal{S}_v = \{\text{a representative set of all flat modules of cardinality } \leq \text{card}(R(v)) + \aleph_0\}$, respectively. Notice that in the first case, $\mathcal{C}$ is the class all of vector bundles, while in the second, $\mathcal{C}$ is the class all of flat quasi-coherent sheaves. □

If $X = \mathbb{P}^n(R)$ where $R$ is any commutative noetherian ring, then every quasi-coherent sheaf on $X$ is a filtered union of coherent subsheaves, and the family of so-called twisting sheaves $\{\mathcal{O}(n) \mid n \in \mathbb{Z}\}$ generates the category of coherent sheaves on X cf. [19, Corollary 5.18], so $\bigoplus_{n \in \mathbb{Z}} \mathcal{O}(n)$ is a (vector bundle) generator for $\mathcal{Qco}(X)$. So Corollary 1.2 applies to this setting. In particular, we extend here [10, Theorem 6.1] which deals with the case of the projective line.

Finally, we consider the case of restricted Drinfeld vector bundles:

The proof of Corollary 1.4. In view of Theorem 4.4, the proof will be complete once we show

Lemma 4.5. If $R$ is a commutative ring and $M$ and $N$ are $\leq \kappa$-presented flat Mittag-Leffler modules, then so is $N \otimes_R M$.

Proof. It is clear that $N \otimes_R M$ is $\leq \kappa$-presented. Let us check the Mittag-Leffler condition (see Definition 2.5). So let $(M_i \mid i \in I)$ be a family of $R$-modules. Since $N$ is flat Mittag-Leffler the canonical map $N \otimes_R \prod_{i \in I} M_i \to \prod_{i \in I} N \otimes_R M_i$ is a monomorphism. Now since $M$ is flat, we get a monomorphism

$$(M \otimes_R N) \otimes_R \prod_{i \in I} M_i \cong M \otimes_R (N \otimes_R \prod_{i \in I} M_i) \to M \otimes_R (\prod_{i \in I} N \otimes_R M_i).$$

Now we apply the fact that $M$ is Mittag-Leffler to the family $(N \otimes_R M_i \mid i \in I)$ to get a monomorphism

$$M \otimes_R (\prod_{i \in I} N \otimes_R M_i) \to \prod_{i \in I} M \otimes_R (N \otimes_R M_i) \cong \prod_{i \in I} (M \otimes_R N) \otimes_R M_i.$$ 

So the claim follows by composing the previous monomorphisms. □
5. Flat Mittag–Leffler Abelian Groups

Let \( X \) be a scheme having a generating set consisting of Drinfeld vector bundles. We have already seen that restricted Drinfeld vector bundles impose monoidal model structures on \( \mathcal{C}(\mathcal{Qco}(X)) \) whose weak equivalences are the homology isomorphisms (see Corollary 1.4). This result suggests that the entire class of all Drinfeld vector bundles could also impose a cofibrantly generated model structure in \( \mathcal{C}(\mathcal{Qco}(X)) \). The aim of this section is to prove Theorem 1.5 and show thus that this is not the case in general.

We recall that, given a class of objects \( F \) in a Grothendieck category \( A \), an \( F \)-precover of an object \( M \) is a morphism \( \varphi : F \to M \) with \( F \in F \) such that \( \text{Hom}_A(F', F) \to \text{Hom}_A(F', M) \) is an epimorphism for every \( F' \in F \). The class \( F \) is said to be precovering if every object of \( A \) admits an \( F \)-precover (see [12, Chapters 5 and 6] for properties of such classes). For example the class of projective modules \( P \) is precovering. Similarly as \( P \) is used to define projective resolutions, one can employ a precovering class \( F \) to define \( F \)-resolutions and a version of relative homological algebra can be developed (see [12]).

Let \( \mathcal{D} \) denote the class of all flat Mittag–Leffler modules over a ring \( R \). Both the flat and the Mittag–Leffler modules are clearly closed under pure–submodules, hence so is the class \( \mathcal{D} \). Similarly, \( \mathcal{D} \) is closed under (pure) extensions (see [26, 2.1.6]). Moreover, the countably generated modules in \( \mathcal{D} \) are exactly the countably generated projective modules by [26, 2.2.2]. In general, the modules in \( \mathcal{D} \) are characterized by the following theorem from [26] (cf. [2]):

**Theorem 5.1.** Let \( R \) be a ring and \( M \in \text{Mod–} R \). Then the following are equivalent:

1. \( M \) is a flat Mittag-Leffler module.
2. Every finite (or countable) subset of \( M \) is contained in a countably generated projective submodule which is pure in \( M \).
3. Every finite subset of \( M \) is contained in a projective submodule which is pure in \( M \).

This theorem implies that the class \( \mathcal{D} \) is closed under \( \mathcal{D} \)-filtrations (see Definition 2.1).

We start with a more specific characterization of flat Mittag–Leffler modules in the particular case of Dedekind domains with countable spectrum. Recall that a module \( M \) over a right hereditary ring is \( \aleph_1 \)-projective (\( \aleph_1 \)-free) provided that each countably generated submodule of \( M \) is projective (free).

**Lemma 5.2.** Assume that \( R \) is a Dedekind domain such that \( \text{Spec}(R) \) is countable. Let \( M \in \text{Mod–} R \). Then \( M \in \mathcal{D} \) iff \( M \) is \( \aleph_1 \)-projective.

**Proof.** If \( M \in \mathcal{D} \) and \( C \) is a countably generated submodule of \( M \), then \( C \) is contained in a countably generated projective (and pure) submodule \( P \) of \( M \) by Theorem 5.1. Since \( R \) is right hereditary, \( C \) is also projective.

In order to prove the converse, in view of Theorem 5.1, it suffices to prove that each countable subset \( C \) is contained in a countably generated pure submodule \( P \) of \( M \). Since \( M \) is flat and \( P \) is projective, the purity of the embedding \( P \subseteq M \) can be tested only w.r.t. all simple modules by [17, Lemma 11], that is, one only has to construct a countably generated module \( P \supseteq C \) such that \( P \otimes_R S \to M \otimes_R S \) is monic for each simple left module \( S \). But the class of all simple modules has a countable set of representatives by assumption, so we obtain our claim by applying [29, I.8.8].

From now on, we will restrict ourselves to the particular case of (abelian) groups. By Lemma 5.2, a group \( A \) is flat and Mittag–Leffler iff \( A \) is \( \aleph_1 \)-free. Our aim is
to show that the class of all $\aleph_1$–free groups is not precovering. We will prove this following an idea from [6] where the analogous result was proven consistent with (but independent of) ZFC + GCH for the subclass of $\mathcal{D}$ consisting of all Whitehead groups.

The reason why our result on $\mathcal{D}$ holds in ZFC rather than only in some of its forcing extensions rests in the following fact whose proof goes back to [23] (see also [15]): for each non–cotorsion group $A$, there is a Baer–Specker group (that is, the product $\mathbb{Z}^\kappa$ for some $\kappa \geq \aleph_0$) such that $\operatorname{Ext}^1_\mathbb{Z}(\mathbb{Z}^\kappa, A) \neq 0$; moreover, the Baer–Specker group can be taken small in the following sense:

**Lemma 5.3.** Define a sequence of cardinals $\kappa_\alpha$ ($\alpha \geq 0$) as follows:

1. $\kappa_0 = \aleph_0$,
2. $\kappa_{\alpha+1} = \sup_{\kappa < \alpha} \kappa_\alpha$ whenever $\kappa_{\alpha} = \kappa$, and
3. $\kappa_\alpha = \sup_{\beta < \alpha} \kappa_\beta$ when $\alpha$ is a limit ordinal.

Let $\alpha$ be an ordinal and $A$ be a non–cotorsion group of cardinality $\leq 2^{\kappa_\alpha}$. Then $\operatorname{Ext}^1_\mathbb{Z}(\mathbb{Z}^{\kappa_\alpha}, A) \neq 0$.

**Proof.** This is a consequence of [15, 1.2(4)] where the following stronger assertion is proven:

If $A$ is any group of cardinality $\leq 2^{\kappa_\alpha}$ such that $\operatorname{Ext}^1_\mathbb{Z}(D_{\kappa_\alpha}, A) = 0$ (where $D_{\kappa_\alpha}$ is a certain subgroup of $\mathbb{Z}^{\kappa_\alpha}$) then $\operatorname{Ext}^1_\mathbb{Z}(\mathbb{Z}^{\kappa_\alpha}, A) = 0$, that is, $A$ is a cotorsion group.

**Remark 5.4.** Under GCH, the definition of the $\kappa_\alpha$'s simplifies as follows: if $\kappa_\alpha = \aleph_\beta$, then $\kappa_{\alpha+1} = \aleph_{\beta+\omega}$.

It follows that though the class $\mathcal{D}$ of all $\aleph_1$–free groups is closed under $\mathcal{D}$–filtrations, it is not of the form $^+\mathcal{C}$ for any class of groups $\mathcal{C}$.

**Theorem 5.5.** Let $R = \mathbb{Z}$. Then $\mathcal{D} \neq {^+\mathcal{C}}$, for each class $\mathcal{C} \subseteq \operatorname{Mod} \mathbb{Z}$. In fact, $^+(\mathcal{D}_+)$ is the class of all flat (= torsion-free) groups.

**Proof.** Since all the Baer–Specker groups are $\aleph_1$–free (see e.g. [5, IV.2.8]), Lemma 5.3 implies that $\mathcal{D}_+$ coincides with the class of all cotorsion groups, so $^+(\mathcal{D}_+)$ is the class of all flat groups. Since $\mathbb{Q} \notin \mathcal{D}$, we have $\mathcal{D} \neq {^+\mathcal{C}}$ for each class $\mathcal{C} \subseteq \operatorname{Mod} \mathbb{Z}$.

**Lemma 5.6.** Let $\alpha$ be an ordinal and $A$ be an $\aleph_1$–free group of cardinality $\leq 2^{\kappa_\alpha}$ where $\kappa_\alpha$ is defined as in Lemma 5.3. Then $\operatorname{Ext}^1_\mathbb{Z}(\mathbb{Z}^{\kappa_\alpha}, A) \neq 0$.

**Proof.** In view of Lemma 5.3, it suffices to verify that no non–zero $\aleph_1$–free group is cotorsion. Indeed, each reduced torsion free cotorsion group $A$ has a direct summand isomorphic to $\mathbb{Z}_p$ (the group of all $p$–adic integers for some prime $p \in \mathbb{Z}$) by [5, V.2.7 and V.2.9(5),(6)]. However, if $A$ is $\aleph_1$–free, then it is cotorsion–free by [5, V.2.10(ii)], so $\mathbb{Z}_p$ does not embed into $A$.

**Remark 5.7.** Theorem 5.5 already implies that we cannot improve Corollary 1.4 by extending the claim to all Drinfeld vector bundles (that is, removing the $\kappa$–filtration restriction): consider the affine scheme $X = \operatorname{Spec}(\mathbb{Z})$. Then there is a category equivalence $\Omega\mathfrak{f}(X) \cong \operatorname{Mod}(\mathbb{Z})$ by [19, Corollary 5.5]. By Theorem 5.5, for each infinite cardinal $\kappa$, there is a Drinfeld vector bundle $\mathcal{M}$ which does not have a $\mathcal{C}$–filtration where $\mathcal{C}$ is the class of all locally $\leq \kappa$–presented Drinfeld vector bundles.

In more detail, if $\kappa = \kappa_\alpha$ (see Lemma 5.3) and $\mathcal{D}^{\leq \kappa_\alpha}$ denotes the class of all $\leq \kappa_\alpha$–generated $\aleph_1$–free groups, then $\mathbb{Z}^{\kappa_\alpha} \in \mathcal{D}^{\leq \kappa_\alpha}$.

Indeed, denote by $\mathcal{E}$ a representative set of elements of the class $\mathcal{D}^{\leq \kappa_\alpha}$. Then $|\mathcal{E}| \leq 2^{\kappa_\alpha}$, so by [7, Theorem 2], there exists $A \in \mathcal{E}_+$ such that $|A| = 2^{\kappa_\alpha}$ and $A$ has an $\mathcal{E}$–filtration. In particular, $A$ is $\aleph_1$–free, and $\operatorname{Ext}^1_\mathbb{Z}(\mathbb{Z}^{\kappa_\alpha}, A) \neq 0$ by Lemma 5.6. Hence $\mathbb{Z}^{\kappa_\alpha} \notin {^+(\mathcal{E}_+)}$. 

In view of Remark 5.7, the class of all \( \mathbb{N}_1 \)-free groups cannot induce a cofibrantly generated model category structure on \( \Sigma\text{co}(\text{Spec}(\mathbb{Z})) \) \( \cong \text{Mod} - \mathbb{Z} \) compatible with its abelian structure. This is the second claim of Theorem 1.5. In order to prove the (stronger) first claim of Theorem 1.5, it remains to show the following.

**Theorem 5.8.** The class of all \( \mathbb{N}_1 \)-free groups is not precovering.

**Proof.** Assume there exists a \( \mathcal{D} \)-precover of \( \mathbb{Q} \), and denote it by \( f : B \to \mathbb{Q} \). We will construct an \( \mathbb{N}_1 \)-free group \( G \) of infinite rank such that there is no non-zero homomorphism from \( G \) to \( B \). Since \( G \) has infinite rank and \( \mathbb{Q} \) is injective, there is a non-zero (even surjective) homomorphism \( g : G \to \mathbb{Q} \). Clearly \( g \) does not factorize through \( f \), a contradiction.

First, we take an ordinal \( \alpha \) such that \( \mu = 2^{\alpha} \geq \text{card}(B) \) (see Lemma 5.3). The \( \mathbb{N}_1 \)-free group \( G \) will be the last term of a continuous chain of \( \mathbb{N}_1 \)-free groups of infinite rank, \( (G_\nu \mid \nu \leq \tau) \), of length \( \tau \geq \mu^+ \). The chain will be constructed by induction on \( \nu \) as follows: first, \( G_0 \) is any free group of infinite rank.

Assume \( G_\nu \) is defined for some \( \nu < \mu^+ \) and consider the set \( I_\nu \) of all non-zero homomorphisms from \( G_\nu \) to \( B \). If \( I_\nu = \emptyset \), we put \( \tau = \nu \) and finish the construction. Otherwise, we fix a free presentation \( 0 \to K \hookrightarrow F \to \mathbb{Z}^\alpha \to 0 \) of \( \mathbb{Z}^\alpha \), and denote by \( \theta \) the inclusion of \( K \) into \( F \).

For each \( h \in I_\nu \), let \( A_h \) be the image of \( h \). By Lemma 5.6, \( \text{Ext}^1(\mathbb{Z}^\alpha, A_h) \neq 0 \), so there exists a homomorphism \( \phi_h : K \to A_h \) which does not extend to \( F \). Since \( K \) is free and \( h \) maps onto \( A_h \), there is a homomorphism \( \psi_h : G \to G_\nu \) such that \( h\psi_h = \phi_h \).

Denote by \( \Theta \) the inclusion of \( K(I_\nu) \) into \( F(I_\nu) \), and define \( \Psi \in \text{Hom}_\mathbb{Z}(K(I_\nu), G_\nu) \) so that the \( h \)-th component of \( \Psi \) is \( \psi_h \), for each \( h \in I_\nu \).

The group \( G_{\nu+1} \) is defined by the pushout of \( \Theta \) and \( \Psi \):

\[
\begin{array}{ccc}
K(I_\nu) & \xrightarrow{\Theta} & F(I_\nu) \\
\downarrow \Psi & & \downarrow \Omega \\
G_\nu & \xrightarrow{\phi} & G_{\nu+1}.
\end{array}
\]

Note that \( G_{\nu+1}/G_\nu \cong F(I_\nu)/K(I_\nu) \) is \( \mathbb{N}_1 \)-free because \( \mathbb{Z}^\alpha \) is \( \mathbb{N}_1 \)-free by [5, IV.2.8]. It follows that \( G_\nu \) is an \( \mathbb{N}_1 \)-free group of infinite rank.

If \( \nu < \mu^+ \) is a limit ordinal we put \( G_\nu = \bigcup_{\sigma < \nu} G_\sigma \). Clearly \( G_\nu \) has infinite rank, and since \( G_{\sigma+1}/G_\sigma \) is \( \mathbb{N}_1 \)-free for each \( \sigma < \nu \) by construction, \( G_\nu \) is also \( \mathbb{N}_1 \)-free.

It remains to show that there exists \( \nu < \mu^+ \) such that \( I_\nu = \emptyset \). Assume \( I_\nu \neq \emptyset \) for all \( \nu < \mu^+ \) (hence \( G_\nu \) is defined for all \( \nu < \mu^+ \)); we will prove that \( I_{\mu^+} = \emptyset \).

Assume there is a non-zero homomorphism \( f : G_{\mu^+} \to B \) and let \( \nu < \mu^+ \) be such that \( h := f \upharpoonright G_\nu \neq 0 \).

Using the notation introduced in the non-limit step of the construction, we will prove that \( A_h \) is a proper submodule of the image of \( h' = f \upharpoonright G_{\nu+1} \). If not, then \( h' \Omega \) extends \( h' \Psi \) to a homomorphism \( F(I_\nu) \to A_h \). Denote by \( \iota_h \) and \( \iota_h' \) the \( h \)-th canonical embedding of \( K \) into \( K(I_\nu) \) and of \( F \) into \( F(I_\nu) \), respectively. Then \( h' \Omega \iota_h' \) extends \( h' \iota_h \rightarrow h' \Psi \iota_h = h' \phi_h \) to a homomorphism \( F \to A_h \), in contradiction with the definition of \( \phi_h \).

This proves that the image of \( f \upharpoonright G_\nu \) is a proper submodule of the image of \( f \upharpoonright G_{\nu+1} \) for each \( \nu \in \mathcal{C} \), where \( \mathcal{C} \) is the set of all \( \nu < \mu^+ \) such that \( f \upharpoonright G_\nu \neq 0 \). However, \( f \neq 0 \) implies that \( \mathcal{C} \) has cardinality \( \mu^+ \), in contradiction with \( \text{card}(B) < \mu^+ \). This proves that \( \text{Hom}_\mathbb{Z}(G_{\mu^+}, B) = 0 \), that is, \( I_{\mu^+} = \emptyset \). \( \square \)
